

# Connective motivic Chern classes of Schubert cells

Raj Gandhi, Cornell University

## The connective motivic Segre classes

Consider the following  $\mathbb{Z}[\beta][q^{\pm 1}]$ -linear operators on  $\mathbb{Z}[\beta][e^{\pm y_1}, \dots, e^{\pm y_n}, q^{\pm 1}]$ :

$$\partial_i := \frac{\beta(1-q^2)}{1-e^{y_{i+1}-y_i}} + \frac{\beta(1-q^2)+q^2(1-e^{y_i-y_{i+1}})}{1-e^{y_i-y_{i+1}}} r_i,$$

which satisfy:

- 1.  $\partial_i \circ \partial_j = \partial_j \circ \partial_i$  for all  $i, j = 1, \dots, n-1$  such that  $|i-j| > 1$ .
- 2.  $\partial_i \circ \partial_{i+1} \circ \partial_i = \partial_{i+1} \circ \partial_i \circ \partial_{i+1}$  for all  $i = 1, \dots, n-2$ .
- 3.  $(\partial_i + q^2) \circ (\partial_i + (q^2\beta - q^2 - \beta)) = 0$  for all  $i = 1, \dots, n-1$ .

Let  $\Gamma$  be the set of 01 sequences with  $k$  1s and  $n-k$  0s. Consider the ring

$$R := \bigoplus_{\lambda \in \Gamma} \text{Frac}(\mathbb{Z}[\beta][e^{\pm y_1}, \dots, e^{\pm y_n}, q^{\pm 1}]).$$

The group  $S_n$  acts on  $R$  by  $w \cdot (f_\lambda)_\lambda := (w(f_\lambda))_{w(\lambda)}$ ,  $w \in S_n$ . Set  $\omega := 11 \dots 100 \dots 0$ .

$$S_\omega|_\lambda := \begin{cases} \prod_{i>j:\lambda_i<\lambda_j} \frac{1-e^{y_i-y_j}}{\beta(1-q^2)+q^2(1-e^{y_i-y_j})}, & \text{if } \lambda = \omega; \\ 0, & \text{otherwise.} \end{cases}$$

The other  $S_\lambda$  are defined by the rule  $S_{w^{-1}(\omega)} := \partial_w(S_\omega)$ . At  $\beta = 1$ , the  $S_\lambda$  are the motivic Segre classes of Schubert cells. At  $\beta \rightarrow 0$ , the  $S_\lambda$  are the SSM classes of Schubert cells.

## Knutson-Tao puzzles

Define  $Q(\beta) := q^2 + \beta - q^2\beta$ . For  $\lambda \in \mathbb{Z}[y_1, \dots, y_n]$ , set

$$y_\lambda := \beta(1-q^2) + q^2(1-e^\lambda).$$

A **puzzle** with side labels  $\lambda, \mu, \nu$  in  $\Gamma$  is a triangle with side labels  $\lambda, \mu, \nu$  that is tiled by the following **puzzle pieces** with edge labels 0, 1, and 10. Each puzzle piece comes with a function  $\mathbb{Z}[y_1, \dots, y_n] \rightarrow \text{Frac}(\mathbb{Z}[\beta][e^{\pm y_1}, \dots, e^{\pm y_n}, q^{\pm 1}])$  called its **fugacity**:

$$\begin{array}{cccccc} \begin{array}{c} 0 \\ \diagdown \diagup \\ 0 \end{array} = 1 & \begin{array}{c} 1 \\ \diagdown \diagup \\ 1 \end{array} = 1 & \begin{array}{c} 1 \\ \diagdown \diagup \\ 0 \end{array} = 1 & \begin{array}{c} 10 \\ \diagdown \diagup \\ 10 \end{array} = 1 & \begin{array}{c} 0 \\ \diagdown \diagup \\ 10 \end{array} = 1 & \begin{array}{c} 0 \\ \diagdown \diagup \\ 0 \end{array} = 1 \\ \begin{array}{c} 0 \\ \diagdown \diagup \\ 10 \end{array} = \frac{\beta(1-q^2)}{y_\lambda} & \begin{array}{c} 1 \\ \diagdown \diagup \\ 10 \end{array} = \frac{\beta(1-q^2)}{y_\lambda} & \begin{array}{c} 0 \\ \diagdown \diagup \\ 1 \end{array} = \frac{q(1-e^\lambda)}{y_\lambda} & \begin{array}{c} 1 \\ \diagdown \diagup \\ 0 \end{array} = \frac{q(1-e^\lambda)}{y_\lambda} & \begin{array}{c} 1 \\ \diagdown \diagup \\ 10 \end{array} = \frac{\beta q(q^2-1)}{y_\lambda} & \begin{array}{c} 0 \\ \diagdown \diagup \\ 0 \end{array} = \frac{\beta q(q^2-1)}{y_\lambda} \\ \begin{array}{c} 0 \\ \diagdown \diagup \\ 1 \end{array} = \frac{\beta(1-q^2)e^\lambda}{y_\lambda} & \begin{array}{c} 10 \\ \diagdown \diagup \\ 0 \end{array} = \frac{\beta(1-q^2)e^\lambda}{y_\lambda} & \begin{array}{c} 10 \\ \diagdown \diagup \\ 0 \end{array} = \frac{qQ(\beta)(1-e^\lambda)}{y_\lambda} & \begin{array}{c} 0 \\ \diagdown \diagup \\ 10 \end{array} = \frac{qQ(\beta)(1-e^\lambda)}{y_\lambda} & \begin{array}{c} 1 \\ \diagdown \diagup \\ 10 \end{array} = \frac{qQ(\beta)(1-e^\lambda)}{y_\lambda} & \begin{array}{c} 10 \\ \diagdown \diagup \\ 1 \end{array} = \frac{qQ(\beta)(1-e^\lambda)}{y_\lambda} \\ \begin{array}{c} 1 \\ \diagdown \diagup \\ 10 \end{array} = \frac{qQ(\beta)(1-e^\lambda)}{y_\lambda} & \begin{array}{c} 10 \\ \diagdown \diagup \\ 1 \end{array} = \frac{\beta Q(\beta)(q^2-1)e^\lambda}{qy_\lambda} & \begin{array}{c} 10 \\ \diagdown \diagup \\ 10 \end{array} = \frac{qQ(\beta)(1-e^\lambda)}{y_\lambda} & \begin{array}{c} 0 \\ \diagdown \diagup \\ 10 \end{array} = \frac{qQ(\beta)(1-e^\lambda)}{y_\lambda} & \begin{array}{c} 1 \\ \diagdown \diagup \\ 10 \end{array} = \frac{qQ(\beta)(1-e^\lambda)}{y_\lambda} & \begin{array}{c} 10 \\ \diagdown \diagup \\ 10 \end{array} = \frac{qQ(\beta)(1-e^\lambda)}{y_\lambda} \\ \begin{array}{c} 0 \\ \diagdown \diagup \\ 0 \end{array} = 1 & \begin{array}{c} 1 \\ \diagdown \diagup \\ 1 \end{array} = 1 & \begin{array}{c} 0 \\ \diagdown \diagup \\ 10 \end{array} = 1 & \begin{array}{c} 10 \\ \diagdown \diagup \\ 0 \end{array} = 1 & \begin{array}{c} 1 \\ \diagdown \diagup \\ 0 \end{array} = 1 & \begin{array}{c} 10 \\ \diagdown \diagup \\ 10 \end{array} = \frac{-Q(\beta)}{q} \\ \begin{array}{c} 0 \\ \diagdown \diagup \\ 0 \end{array} = 1 & \begin{array}{c} 1 \\ \diagdown \diagup \\ 1 \end{array} = 1 & \begin{array}{c} 10 \\ \diagdown \diagup \\ 0 \end{array} = 1 & \begin{array}{c} 10 \\ \diagdown \diagup \\ 10 \end{array} = 1 & \begin{array}{c} 1 \\ \diagdown \diagup \\ 0 \end{array} = 1 & \begin{array}{c} 10 \\ \diagdown \diagup \\ 10 \end{array} = -q \end{array}$$

The bottom row of a puzzle is always tiled by the triangle puzzle pieces, and the rest of the puzzle is tiled by (not rotated) rhombus puzzle pieces. The **fugacity of a puzzle** is the product of fugacities of the rhombi and triangles that tile it. A triangle tile has constant fugacity, whereas the fugacity of a rhombus tile depends on its position in the puzzle. A rhombus tile that lies in the  $i$ -th southwest-to-northeast diagonal and the  $j$ -th northwest-to-southeast diagonal depends on  $\lambda = -(y_i - y_j)$ . For example, the fugacity of the puzzle below is  $\frac{qQ(\beta)(1-e^{y_2-y_1})}{\beta(1-q^2)+q^2(1-e^{y_2-y_1})} \cdot \frac{\beta q(q^2-1)}{\beta(1-q^2)+q^2(1-e^{y_3-y_1})} \cdot 1$ .

## Multiplying the connective Segre classes

We will use the notation  $\sum_{\lambda \leftarrow \mu}$  to mean the sum over the fugacities of all possible puzzles with the prescribed boundary labels. The **length**  $l(\lambda)$  of an element  $\lambda \in \Gamma$  is the minimal number of simple transpositions needed to turn  $\lambda$  into  $0^{n-d}1^d$ .

### THEOREM

The product of two classes  $q^{l(\lambda)}S_\lambda$  and  $q^{l(\mu)}S_\mu$  is given by the "puzzle" formula

$$(q^{l(\lambda)}S_\lambda)(q^{l(\mu)}S_\mu) = \sum_{\nu} \sum_{\lambda \leftarrow \mu} q^{l(\nu)}S_\nu.$$

The structure coefficients **positive**, and are sums of products of these factors:

$$-q^\pm \quad Q(\beta) \quad e^{y_j-y_i} \quad \frac{\beta(1-q^2)}{\beta(1-q^2)+q^2(1-e^{y_j-y_i})} \quad -\frac{1-e^{y_j-y_i}}{\beta(1-q^2)+q^2(1-e^{y_j-y_i})}$$

## Example

Let us compute the classes  $q \cdot S_{10}$  and  $S_{01}$  for  $T^*(\text{Gr}(1, 2))$ . The classes are

$$q \cdot S_{10} = q \cdot \left[ 0, \frac{1-e^{y_2-y_1}}{\beta(1-q^2)+q^2(1-e^{y_2-y_1})} \right]; \quad S_{01} = \left( \frac{1}{q} \partial_\alpha \right) (q \cdot S_{10}) = \left[ 1, \frac{\beta(1-q^2)}{\beta(1-q^2)+q^2(1-e^{y_2-y_1})} \right].$$

Let us now multiply classes together:

$$(q \cdot S_{10})^2 = \frac{q(1-e^{y_2-y_1})}{\beta(1-q^2)+q^2(1-e^{y_2-y_1})} (q \cdot S_{10}); \quad (q \cdot S_{10})S_{01} = S_{01}(q \cdot S_{10}) = \frac{\beta(1-q^2)}{\beta(1-q^2)+q^2(1-e^{y_2-y_1})} (q \cdot S_{10});$$

$$S_{01}^2 = S_{01} + \frac{\beta q(q^2-1)}{\beta(1-q^2)+q^2(1-e^{y_2-y_1})} (q \cdot S_{10}).$$

The puzzles give the same result:

$$\begin{array}{ccc} \begin{array}{c} 0 \\ \diagdown \diagup \\ 0 \end{array} = \frac{q(1-e^{y_2-y_1})}{\beta(1-q^2)+q^2(1-e^{y_2-y_1})}; & \begin{array}{c} 0 \\ \diagdown \diagup \\ 10 \end{array} = \frac{\beta(1-q^2)}{\beta(1-q^2)+q^2(1-e^{y_2-y_1})}; & \\ \begin{array}{c} 1 \\ \diagdown \diagup \\ 0 \end{array} = \frac{\beta(1-q^2)}{\beta(1-q^2)+q^2(1-e^{y_2-y_1})}; & \begin{array}{c} 1 \\ \diagdown \diagup \\ 1 \end{array} = 1; & \\ \begin{array}{c} 1 \\ \diagdown \diagup \\ 10 \end{array} = \frac{\beta q(q^2-1)}{\beta(1-q^2)+q^2(1-e^{y_2-y_1})}. & & \end{array}$$

## R-matrix recursion

The classes  $\bar{S}_\lambda := q^{l(\lambda)}S_\lambda$  are characterized by the following properties:

- 1. **Triangularity:**  $\bar{S}_\lambda|_\sigma = 0$  unless  $\sigma \geq \lambda$  in the Bruhat order.
- 2. **Diagonal entries:**

$$\bar{S}_\lambda|_\lambda = \prod_{i<j:\lambda_i>\lambda_j} \frac{q(1-e^{y_i-y_j})}{Q(\beta, q) - q^2 e^{y_i-y_j}}$$

- 3. **Exchange relation:**

$$r_i \bar{S}_\lambda|_{\sigma r_i} = \begin{cases} \frac{\beta(1-q^2)}{Q(\beta, q) - q^2 e^{y_i-y_{i+1}}} \bar{S}_\lambda|_\sigma + \frac{qQ(\beta, q)(1-e^{y_i-y_{i+1}})}{Q(\beta, q) - q^2 e^{y_i-y_{i+1}}} \bar{S}_{\lambda r_i}|_\sigma & \lambda_i < \lambda_{i+1} \\ \bar{S}_\lambda|_\sigma & \lambda_i = \lambda_{i+1} \\ \frac{\beta(1-q^2)(e^{y_i-y_{i+1}})}{Q(\beta, q) - q^2 e^{y_i-y_{i+1}}} \bar{S}_\lambda|_\sigma + \frac{q(1-e^{y_i-y_{i+1}})}{Q(\beta, q) - q^2 e^{y_i-y_{i+1}}} \bar{S}_{\lambda r_i}|_\sigma & \lambda_i > \lambda_{i+1} \end{cases}$$

This recursion is derived from the representation theory of the **multiparameter quantum group** of type  $\hat{a}_2$ .

## Multi-parameter quantum group

The **multi-parameter quantum group**  $U_q(\hat{a}_n)$  is the associative unital algebra over  $\mathbb{K} = \mathbb{Q}(q, j)$  generated by elements  $E_i, F_i, K_i^{(1)}, (K_i^{(1)})^{-1}, K_i^{(2)}, (K_i^{(2)})^{-1}$ , where  $i = 0, 1, \dots, n$ , subject to the relations:

- 1.  $K_i^{(2)}(K_i^{(2)})^{-1} = (K_i^{(2)})^{-1}K_i^{(2)} = 1, \quad K_i^{(1)}(K_i^{(1)})^{-1} = (K_i^{(1)})^{-1}K_i^{(1)} = 1,$
- 2.  $K_i^{(1)}K_j^{(2)} = K_j^{(2)}K_i^{(1)}, \quad K_i^{(1)}K_j^{(1)} = K_j^{(1)}K_i^{(1)}, \quad K_i^{(2)}K_j^{(2)} = K_j^{(2)}K_i^{(2)},$
- 3.  $K_i^{(1)}E_j(K_i^{(1)})^{-1} = q_{i,j}E_j, \quad (K_i^{(2)})^{-1}E_jK_i^{(2)} = q_{j,i}^{-1}E_j,$
- 4.  $K_i^{(1)}F_j(K_i^{(1)})^{-1} = q_{i,j}^{-1}F_j, \quad (K_i^{(2)})^{-1}F_jK_i^{(2)} = q_{j,i}F_j,$
- 5.  $[E_i, F_j] = \delta_{i,j} \frac{q_{i,j}}{q_{i,i-1}} (K_i^{(1)} - (K_i^{(2)})^{-1}),$
- 6.  $E_i^2 E_j - q_{i,j}(1+q_{i,i})E_i E_j E_i + \frac{q_{i,j}}{q_{i,i}} E_j E_i^2 = 0, \quad i \neq j,$
- 7.  $\frac{q_{i,j}}{q_{i,i}} F_i^2 F_j - q_{i,j}(1+q_{i,i})F_i F_j F_i + F_j F_i^2 = 0, \quad i \neq j.$

### THEOREM

The matrix of puzzle fugacities is an  $R$ -matrix for  $U_q(\hat{a}_2)$ :  $R(z) = \left( \text{fug} \left( \begin{array}{c} \diagdown \diagup \\ \diagup \diagdown \end{array} \right) \right)$

## Equivariant connective K-theory

**Equivariant connective K-theory**  $\text{CK}(-)$  is a generalized cohomology theory that interpolates between equivariant Chow rings ( $\beta = 0$ ) and equivariant K-theory ( $\beta = 1$ ). Let  $T = (\mathbb{C}^\times)^n$  be a torus, and  $X$  a smooth  $T$ -variety.

### WORK IN PROGRESS (with Anubhav Nanavaty)

- There is a **connective motivic Chern transformation**

$$\text{CMC}: K_0^T(\text{Var}/X) \rightarrow \text{CK}_T(X) \otimes \mathbb{Z}[y].$$

- Consider the Grassmannian  $\text{Gr}(k, n) = \sqcup_{\lambda \in \Gamma} X_\lambda^\circ$ , where  $X_\lambda^\circ$  are the Schubert cells. The torus  $T$  acts on each Schubert cell  $X_\lambda^\circ$ . We have

$$\text{CMC}(X_\lambda^\circ) = S_\lambda.$$

- There is an Atiyah-Segal isomorphism between  $\text{CK}_T(X)$  and a quotient of the  $T$ -equivariant algebraic cobordism ring of  $X$ , when  $X$  is equivariantly filtrable.

## FUTURE WORK

- Compute the product of two  $S_\lambda$  classes using **quantum multiplication** in  $\text{CK}_T(X_\lambda^\circ)$ .
- Study torus-equivariant connective  $K$ -rings of Nakajima quiver varieties. Are these rings representations for multiparameter quantum groups?
- More generally, study torus-equivariant algebraic cobordism rings of Nakajima quiver varieties. What Hopf algebra will arise?
- Can stable envelopes be defined for the equivariant connective  $K$ -rings of symplectic resolutions?
- Generalize the puzzle formula to 2, 3, and 4-step flag varieties, and separated descents.
